

WESTMOUNT HILLS RESIDENTS ASSOCIATION

April 16, 2012

To the members of the City of London Planning and Environment Committee:

We are writing to oppose and protest the City's aggressive policy of culling all ash trees on public land, which has recently devastated the natural landscape of Tobin Court. During the first week of March, Davey Tree, under contract with the City, cut down **all** but one of the ash trees on Tobin Court - 20 in total - without sufficient prior warning or consultation. These were large, 25 year-old trees with no visible signs of Emerald Ash Borer disease.¹ Their loss has significantly reduced the visual attractiveness of a mature neighbourhood, reduced property values by more than \$300,000 on Tobin Court, and eliminated the substantial ecological and environmental benefits of a well-developed tree canopy.

While the residents are fully aware that the Emerald Ash Borer presents a challenge for the City, we are opposed to the policy of automatically cutting down all ash trees when more cost-effective preventive measures using pesticides are possible. The City would both save money by injecting trees rather than by cutting them down, and would allow the benefits of the tree-scape to continue.

Unfortunately the damage is now already done on Tobin Court. We request that the City take these immediate steps to help restore the neighbourhood environment:

1. Inject the sole remaining ash tree on Tobin Court with TreeAzin. An independent arborist has recommended that this tree be injected as it is in very good condition
2. Plant **1.5** trees with a minimum trunk diameter of **7 cm** for every lost ash tree on Tobin Court.
3. Plant the new trees in **early Spring** rather than later in the year
4. **Consult** with the residents of Tobin Court regarding choices of tree species and precise planting locations on each property

Reasons for opposition to the City's aggressive EAB management strategy

We urge the City to immediately halt its current EAB management policy of cutting down 96% of all public ash trees in London before similar damage is inflicted on other streets and neighbourhoods. We recommend that the City instead adopt a preventive

¹ The City has not provided to the Association any evidence that the ash trees on Tobin Court were assessed or identified as being infested with EAB before they were cut down.

policy of treating all healthy trees and those with no visible signs of EAB to protect them against infestation. The City should dramatically increase the number of trees currently marked for pesticide injection beyond the current number of 384, which represents just 4% of almost 10,000 ash trees marked for culling (in the Appendix we discuss the troubling issue of how these 384 trees were selected). Oakville, which has a similar EAB issue, is treating 40% of its public ash trees – 10 times the proportion in London.

The City should inject every eligible tree on streets and in parks – an estimated population of 3,570 trees.² This could save more than 35% of London’s public ash trees.

City staff – not Davey Tree - should inspect all public ash trees and make decisions about which trees to cut down and which ones to save through injection, based on objective and transparent criteria. City staff should visibly mark trees noted for cutting several weeks before the cutting so that residents have due warning. We outline the rationale for our recommendations below:

1. **The City’s policy is based on a biased consultant’s report.** The City’s policy of culling virtually all ash trees is based on the recommendations contained in a September 2011 report by Davey Resources, a division of the Davey Tree company. Davey has an incentive to advocate for a policy that they benefit from financially, which suggests cutting down more rather than fewer trees. Davey now has a multi-million dollar contract to cut down ash trees in the City. The report’s recommendations should not be treated as independent.
2. **The cost of inoculating trees against EAB with pesticides is less than the cost of cutting down and replacing trees.** According to numbers provided in the Davey Report, the cost of injecting eligible trees with TreeAzin, which has proven very effective at preventing EAB, is \$168 every 2 years for a 28cm diameter tree.³ This cost would likely be reduced should the City adopt a large-scale injection program. Over a ten year period, the total cost of injecting a typical tree would thus be, at most, \$839.⁴ Importantly, and as the Oakville EAB

² According to the Davey Resources September 2011 report (page 21), there are 3,570 ash trees on streets and in parks that are in Fair, Good or Excellent condition, and that have a trunk diameter greater than 15cm. Insecticide treatment on these trees would help prevent infestation with EAB.

³ The City estimates the cost of injecting ash trees with TreeAzin is \$6 per cm. The Davey Resources report found there were 2,488 ash trees on streets in London that were in Fair or better condition and with trunk diameters greater than 15 cm (page 27). The average trunk diameter of all these trees is 28cm.

⁴ In reaching the recommendation that the City cut down trees rather than inject them, the Davey Resources report claims a program of injecting trees with TreeAzin would need to extend over 15 years. However, this time period is not supported by credible evidence. BioForest Technologies estimates that injections will instead be required for 6 – 10 years. There is no firm consensus among independent experts about how many years of injections

Management report identifies, cheaper treatments are likely to be developed in the next few years as scientists in the U.S. and Canada develop new and longer-lasting pesticides. Injecting now thus permits future flexibility to adopt such new treatments. By contrast, the estimated cost of cutting down a tree, removing and disposing the trunk, grinding the stump, and purchasing and planting 1.5 new trees (as per City policy) is approximately \$885 – more than the cost of injection.⁵ And it obviously forecloses the opportunity to benefit from future pesticide treatments. On this basis alone, the City should be injecting trees, not cutting them down. The Town of Oakville has also concluded that it is cheaper to treat and save ash trees than to cut them down and replace them.

3. **The City’s policy is based on a flawed consultant’s report that ignores the benefits of retaining healthy trees.** The Davey Resources report is biased towards the recommendation of cutting down 96% of ash trees since it focuses on the *costs* of alternative approaches to managing EAB. The report does not include estimates of the *benefits* of saving ash trees through injection programs. Yet, comprehensive policy recommendations should be based on a full cost-benefit analysis. Although the benefits are hard to quantify, this does not mean that they are not meaningful. In recent years there has been a tremendous amount of academic research that explicitly quantifies the economic benefits of trees.⁶ A local study by researchers at Ryerson University estimated the 25-year value of the environmental benefits per tree of \$1,325, or \$53 annually.⁷ Clearly, the life-time benefit is substantially greater than the cost of preventive injections.

4. **The consultant’s report ignores the negative impact on property values of cutting down trees.** Independent research has also quantified the impact of street trees on private property values, and has found the effects to be significant. A study in Portland, Oregon, found that street trees growing near a house added an average of \$7,020 to its sale price – or 2.4% of the average

will be required as this is a continuous learning process. Once the EAB scourge has peaked, different pesticide application timelines may be appropriate and new treatments will likely surface or be approved as this is a continent-wide problem. Oakville expects to treat trees over the “10-15 year period of EAB to run its course” (page7, Oakville EAB report, June 14, 2011).

⁵ Cost calculation based on estimates provided in Davey Resources report: cutting down a tree (\$205), replacement tree purchase and planting (\$600 for 1.5 replacement trees). We estimate an additional \$30 for stump removal and \$50 for stump grinding. This cost may be an underestimate of the actual true cost. The Town of Oakville estimates the cost of cutting down and replacing at \$1,500 (page 8 of Oakville’s EAB management report at <http://www.oakville.ca/assets/general%20-%20residents/EABReport2011Jun.pdf>)

⁶ Economic benefits stem from energy savings due to shading and microclimate impacts, atmospheric CO₂ reduction, air quality improvement, storm-water runoff mitigation.

⁷ Millward, A. and Sabir, S. 2011. Benefits of a forested urban park: What is the Value of Allan Gardens to the City of Toronto, Canada?

sales price.⁸ On Tobin Court, where the average assessed property value is \$600,000 this implies a loss of \$14,500 per house in property value. In London as a whole, the average house price is approximately \$230,000 – implying a reduction of \$5,500 in property value from the loss of a proximate street ash tree. On this basis, the City will erase more than \$14 million from property values if it continues to cut down all 2, 488 street ash trees.

- 5. Independent expert organizations have endorsed preventive programs of pesticide injection rather than mass culling of trees.** On January 6, 2011, the Coalition for Urban Ash Tree Conservation stated its policy of responding to EAB as follows:

“We the undersigned strongly endorse ash tree **conservation** as a fundamental component of integrated programs to manage emerald ash borer (EAB) in residential and municipal landscapes. **Cost-effective**, environmentally sound EAB treatment protocols are now available that can preserve ash trees through peak EAB outbreaks with healthy canopy intact. Used in association with tree inventories and strategic removal / **replacement of unhealthy ash**, tree conservation will help retain maximum integrity and value of urban forests. This integrated approach to urban EAB management is supported by university scientists with expertise in EAB management, commercial arborists, municipal foresters, public works officials, and non-governmental organizations (NGOs).”⁹ [emphasis added]

This policy statement is signed by independent scientists at Ohio State University, Michigan State University, University of Maryland, Purdue University and the University of Wisconsin.

- 6. Other cities are adopting a more moderate approach.** Oakville has identified 5,700 (40%) of the 14,500 street and park ash trees for treatment.¹⁰ It is only removing ash trees once they display severe signs of EAB infestation – i.e. Oakville is not cutting down healthy ash trees. Burlington has a similar approach. Such a moderate policy is still compatible with safety concerns and is fiscally prudent. We recommend that the City adopt a similar policy of selective removal of trees only that are obviously diseased. This would permit a more gradual replacement of trees as they become infected in neighbourhoods and avoid the sudden shock of losing all trees at one time.
- 7. The City did not provide sufficient warning or consultation to local residents.** The City sent a leaflet to residents indicating that ash trees in the

¹⁰ Oakville’s EAB Management plan is available at <http://www.oakville.ca/assets/general%20-%20residents/EABReport2011Jun.pdf>

neighbourhood may be removed as part of the EAB management plan. However, this provided no indication of the *scale* of the culling that would take place on *Tobin Court*. Had residents known in advance that every ash tree would be cut down then there would have been requests for meetings with the City to discuss the rationale and alternative options – such as using pesticides. In the future, residents should be provided with much more detailed information, especially on such drastic policy proposals that directly and significantly affect residents’ properties.

In summary, the economic benefits of saving street ash trees in residential areas are estimated to be more than \$5,500 in increased property values and \$1,300 in environmental value per tree. The combined benefit of \$6,800 per tree massively outweighs the \$839 cost of injecting eligible trees with pesticide to prevent future EAB infestation. Furthermore, the cost of injecting is less than the \$885 cost of cutting down and replacing trees. For these reasons, we believe there is an overwhelming case for the City of injecting all eligible public ash trees rather than cutting them down.

We look forward to your response.

Sincerely,

Appendix: How did the City decide which ash trees were worthy of saving?

A puzzling feature of the Davey report is why only 384 ash trees were marked for pesticide injections; how did the City decide which trees warranted this treatment?

The report provides little justification for why these 384 trees were selected. As noted above, there are more than 3,500 trees that are eligible for treatment – those that are in 'Fair' or better condition, medium size or larger, and that are located on streets or in parks.

A serious concern arises from inspection of the list of addresses where ash trees were injected with pesticide (pages 87 to 97 of the pdf version of the Davey Resources report). This reveals that certain areas of the city appeared to receive special treatment. For instance, Timber Drive, a residential area in Byron had 43 ash trees injected. The average diameter of these trees is 31cm. How does a single street qualify to receive more than 10% of the injection quota? Why did Tobin Court – which had 20 healthy ash trees with diameters ranging from 40 – 50cm – not receive equivalent pesticide treatment?

There are other examples of small residential areas that had a significant number of medium sized trees injected, for instance around Ambleside Drive, Corley Drive and Buttermere Road; and also around Blackwater Road. In both these neighbourhoods, all healthy ash trees have been treated with pesticide to protect against EAB. At the same time, it is clear that some visibly very unhealthy trees have been injected with pesticide. 19 Buttermere Road is an example: looking at the state of the tree in July 2009 using Google Street View, it is easy to see severe canopy loss, indicating an advanced stage of EAB infestation. So why was this tree injected with pesticide two years later in 2011 when the deterioration would have been even worse?

This raises the concern about inequitable selection of neighbourhoods for ash tree injections.

The City needs a transparent, objective set of criteria for selecting trees for treatment.
